How to Prevent Common Email Typos

Last Modified on 07/02/2026 3:05 pm EDT

The Prevent Common Email Typos extension detects and corrects common email domain mistakes, like gmial.com or yaho.com, before a campaign submission goes through. This reduces bounce rates caused by typos in submitted email addresses.

Step 1: Install the extension

Install the extension once from your Digioh account.

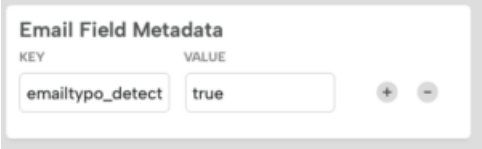

1. Click your account dropdown (top right) and select **Extensions**.
2. Find the **Prevent Common Email Typos** extension and install it.

Once installed, you can use this extension across all your campaigns.

Step 2: Activate typo detection on a field

You enable typo detection at the field level by adding a metadata key to a custom field in your campaign.

1. Open your campaign in the Design Editor.
2. Select the field you're using to collect the user's email (either the default email field or a custom field)
3. Add the following metadata to the field: Email typo_detect : true

4. Save and publish your changes.

Digioh will now detect and prevent submissions containing common email typos.
